

# EF21: A New, Simpler, Theoretically Better, and Practically Faster Error Feedback

Peter Richtárik<sup>1</sup> Igor Sokolov<sup>1</sup> Ilyas Fatkhulin<sup>1, 2</sup>  
<sup>1</sup> KAUST <sup>2</sup> TU Munich

## The problem

We are interested in solving the *nonconvex distributed optimization problem*

$$\min_{x \in \mathbb{R}^d} \left[ f(x) := \frac{1}{n} \sum_{i=1}^n f_i(x) \right], \quad (1)$$

where  $x \in \mathbb{R}^d$  represents the parameters of a machine learning model we wish to train,  $n$  is the number of workers/nodes/machines, and  $f_i(x)$  is the loss of model  $x$  on the data stored on node  $i$ .

## Assumptions

We assume throughout that  $f^{\inf} := \inf_{x \in \mathbb{R}^d} f(x) > -\infty$ .

**Assumption 1 (Lipschitz gradient).**

Every  $f_i$  has  $L_i$ -Lipschitz gradient, i.e.,

$$\|\nabla f_i(x) - \nabla f_i(y)\| \leq L_i \|x - y\| \quad \forall x, y \in \mathbb{R}^d.$$

**Assumption 2 (Polyak-Lojasiewicz).**

There exists  $\mu > 0$  such that  $f(x) - f(x^*) \leq \frac{1}{2\mu} \|\nabla f(x)\|^2$  for all  $x \in \mathbb{R}^d$ , where  $x^* = \arg \min f$ .

## Contractive compressors

**Contractive compressor:** A (possibly randomized) map  $\mathcal{C} : \mathbb{R}^d \rightarrow \mathbb{R}^d$  is called a *contractive compressor* if there exists a constant  $0 < \alpha \leq 1$ :

$$\mathbb{E} [\|\mathcal{C}(x) - x\|^2] \leq (1 - \alpha) \|x\|^2, \quad \forall x \in \mathbb{R}^d. \quad (2)$$

**Example: Top- $k$  (greedy)** sparsification operator keeps the  $k$  largest entries of  $x$  in absolute value, and zeros out the rest. This is a biased contractive compressor with  $\alpha = \frac{k}{d}$ .

## Main goal

Design an efficient **distributed** first-order method that works naturally with **contractive compressors** (which can be biased!) and relies on **standard assumptions** only.

## Generic method

Consider the generic first-order method

$$x^{t+1} = x^t - \frac{\gamma}{n} \sum_{i=1}^n g_i^t, \quad (3)$$

where  $\gamma > 0$  is a learning rate, and  $g_i^t$  is an **easy-to-communicate** (i.e., **compressed**) **approximation of  $\nabla f_i(x^t)$** .

**How to construct the estimators  $g_i^t$  in the generic method?**

- Naive idea
- Good but non-implementable idea
- Good and implementable idea

## Naive idea

Simply use the compressed gradient

$$g_i^t = \mathcal{C}(\nabla f_i(x^t))$$

**Advantages:** • Conceptually easy

- Problems:** •  $\mathbb{E} [\|g_i^t - \nabla f_i(x^t)\|^2] \rightarrow 0$  as  $t \rightarrow \infty$
- As a result, can diverge for  $n > 1$  [1]

## Good but non-implementable idea

Assume that we know  $\nabla f_i(x^*)$  and use

$$g_i^t = \nabla f_i(x^*) + \mathcal{C}(\nabla f_i(x^t) - \nabla f_i(x^*))$$

**Advantages:** •  $\mathbb{E} [\|g_i^t - \nabla f_i(x^t)\|^2] \rightarrow 0$  as  $t \rightarrow \infty$

- As a result, converges for all  $n \geq 1$

**Problems:** • Not implementable since we do not know  $\nabla f(x^*)$

## Good and implementable idea

Define recursively a **Markov compressor**:

$$g_i^0 = \mathcal{C}(\nabla f_i(x^0)), \quad g_i^{t+1} = g_i^t + \mathcal{C}(\nabla f_i(x^{t+1}) - g_i^t)$$

**Advantages:** • Easy to implement

- $\mathbb{E} [\|g_i^t - \nabla f_i(x^t)\|^2] \rightarrow 0$  as  $t \rightarrow \infty$
- As a result, converges for all  $n \geq 1$
- Fast convergence in theory and practice

## EF21 = Generic method + Markov compressor

**Algorithm 1:** EF21 (Error Feedback version 2021)

**Input:**  $x^0 \in \mathbb{R}^d$ ;  $\gamma > 0$ ;  $g_i^0 = \mathcal{C}(\nabla f_i(x^0))$  for  $i = 1, \dots, n$  (known by nodes and the master);  $g^0 = \frac{1}{n} \sum_{i=1}^n g_i^0$  (known by master)  
**for**  $t = 0, 1, \dots, T-1$  **do**  
    Master computes  $x^{t+1} = x^t - \gamma g^t$  and broadcasts  $x^{t+1}$  to all nodes  
    **for all nodes**  $i = 1, \dots, n$  **in parallel do**  
        Compress  $c_i^t = \mathcal{C}(\nabla f_i(x^{t+1}) - g_i^t)$  and send  $c_i^t$  to the master  
        Update local state  $g_i^{t+1} = g_i^t + \mathcal{C}(\nabla f_i(x^{t+1}) - g_i^t)$   
    **end**  
    Master computes  $g^{t+1} = \frac{1}{n} \sum_{i=1}^n g_i^{t+1}$  via  $g^{t+1} = g^t + \frac{1}{n} \sum_{i=1}^n c_i^t$   
**end**

## Relationship between EF and EF21

**Algorithm 2:** EF (Error Feedback version 2014) [2]

**Input:**  $x^0 \in \mathbb{R}^d$ ;  $\gamma > 0$ ;  $e^0 = 0$ ,  $w^0 = \mathcal{C}(\gamma \nabla f(x^0))$   
**for**  $t = 0, 1, 2, \dots, T-1$  **do**  
     $x^{t+1} = x^t - \gamma w^t$   
     $e^{t+1} = e^t + \gamma \nabla f(x^t) - w^t$   
     $w^{t+1} = \mathcal{C}(e^{t+1} + \gamma \nabla f(x^{t+1}))$   
**end**

**Algorithm 3:** EF21 (Single node)

**Input:**  $x^0 \in \mathbb{R}^d$ ;  $\gamma > 0$ ;  $g^0 = \mathcal{C}(\nabla f(x^0))$   
**for**  $t = 0, 1, 2, \dots, T-1$  **do**  
     $x^{t+1} = x^t - \gamma g^t$   
     $g^{t+1} = g^t + \mathcal{C}(\nabla f(x^{t+1}) - g^t)$   
**end**

## Restricted equivalence of EF and EF21

**Theorem 1.** Assume that  $\mathcal{C}$  is **deterministic**, **positively homogeneous** and **additive**. Then EF (Algorithm 2) and EF21 (Algorithm 3) produce the same sequences of iterates  $\{x^t\}_{t \geq 0}$ . The same holds for distributed versions of the methods.

**Remark 1.** The conditions of Theorem 1 are not met for popular compressors used in practice. For example, Top- $k$  compressor is deterministic and positively homogeneous, but **is not additive**.

## EF21+: an improved variant

**Idea:** Use  $\mathcal{C}$  or the Markov compressor, whichever is better.

Compute gradient compressed by the **contractive compressor**

$$b_i^{t+1} = \mathcal{C}(\nabla f_i(x^{t+1})).$$

Compute gradient compressed by the **Markov compressor**

$$m_i^{t+1} = g_i^t + \mathcal{C}(\nabla f_i(x^{t+1}) - g_i^t).$$

Compute distortions:

$$B_i^{t+1} = \|b_i^{t+1} - \nabla f_i(x^{t+1})\|^2, \quad M_i^{t+1} = \|m_i^{t+1} - \nabla f_i(x^{t+1})\|^2.$$

Define local gradient estimator as the best of the two:

$$g_i^{t+1} = \begin{cases} m_i^{t+1} & \text{if } M_i^{t+1} \leq B_i^{t+1} \\ b_i^{t+1} & \text{if } M_i^{t+1} > B_i^{t+1}. \end{cases}$$

## Convergence theory

Define

$$G^t := \frac{1}{n} \sum_{i=1}^n \|g_i^t - \nabla f_i(x^t)\|^2, \quad \tilde{L} := \frac{1}{n} \sum_{i=1}^n L_i^2,$$

$$\theta := 1 - \sqrt{1 - \alpha}, \quad \beta := \frac{1 - \alpha}{1 - \sqrt{1 - \alpha}}.$$

## EF21 for general non-convex functions

**Theorem 2.** Let Assumption 1 hold, and let the stepsize in Algorithm 1 be set as

$$0 < \gamma \leq \left( L + \tilde{L} \sqrt{\frac{\beta}{\theta}} \right)^{-1}. \quad (4)$$

Fix  $T \geq 1$  and let  $\hat{x}^T$  be chosen from the iterates  $x^0, x^1, \dots, x^{T-1}$  uniformly at random. Then

$$\mathbb{E} [\|\nabla f(\hat{x}^T)\|^2] \leq \frac{2(f(x^0) - f^{\inf})}{\gamma T} + \frac{\mathbb{E}[G^0]}{\theta T}. \quad (5)$$

This is the first  $O(1/T)$  rate for error feedback. Best previous rate was  $O(1/T^{2/3})$ , and under strong/unreasonable assumptions.

## EF21 for PL functions

**Theorem 3.** Let Assumptions 1 and 2 hold, and let the stepsize in Algorithm 1 be set as

$$0 < \gamma \leq \min \left\{ \left( L + \tilde{L} \sqrt{\frac{2\beta}{\theta}} \right)^{-1}, \frac{\theta}{2\mu} \right\}. \quad (6)$$

Let  $\Psi^t := f(x^t) - f(x^*) + \frac{\gamma}{2} G^t$ . Then for any  $T \geq 0$ , we have

$$\mathbb{E} [\Psi^T] \leq (1 - \gamma\mu)^T \mathbb{E} [\Psi^0]. \quad (7)$$

This is the first linear rate for error feedback in the distributed setting  $n > 1$  without strong assumptions (such as reliance on over-parameterized regime).

## EF21+ for general non-convex & PL functions

**Theorem 4.** If additionally, the compressor  $\mathcal{C}$  is *deterministic*, then Theorems 2 and 3 hold for EF21+ as well.

## Summary of complexity results

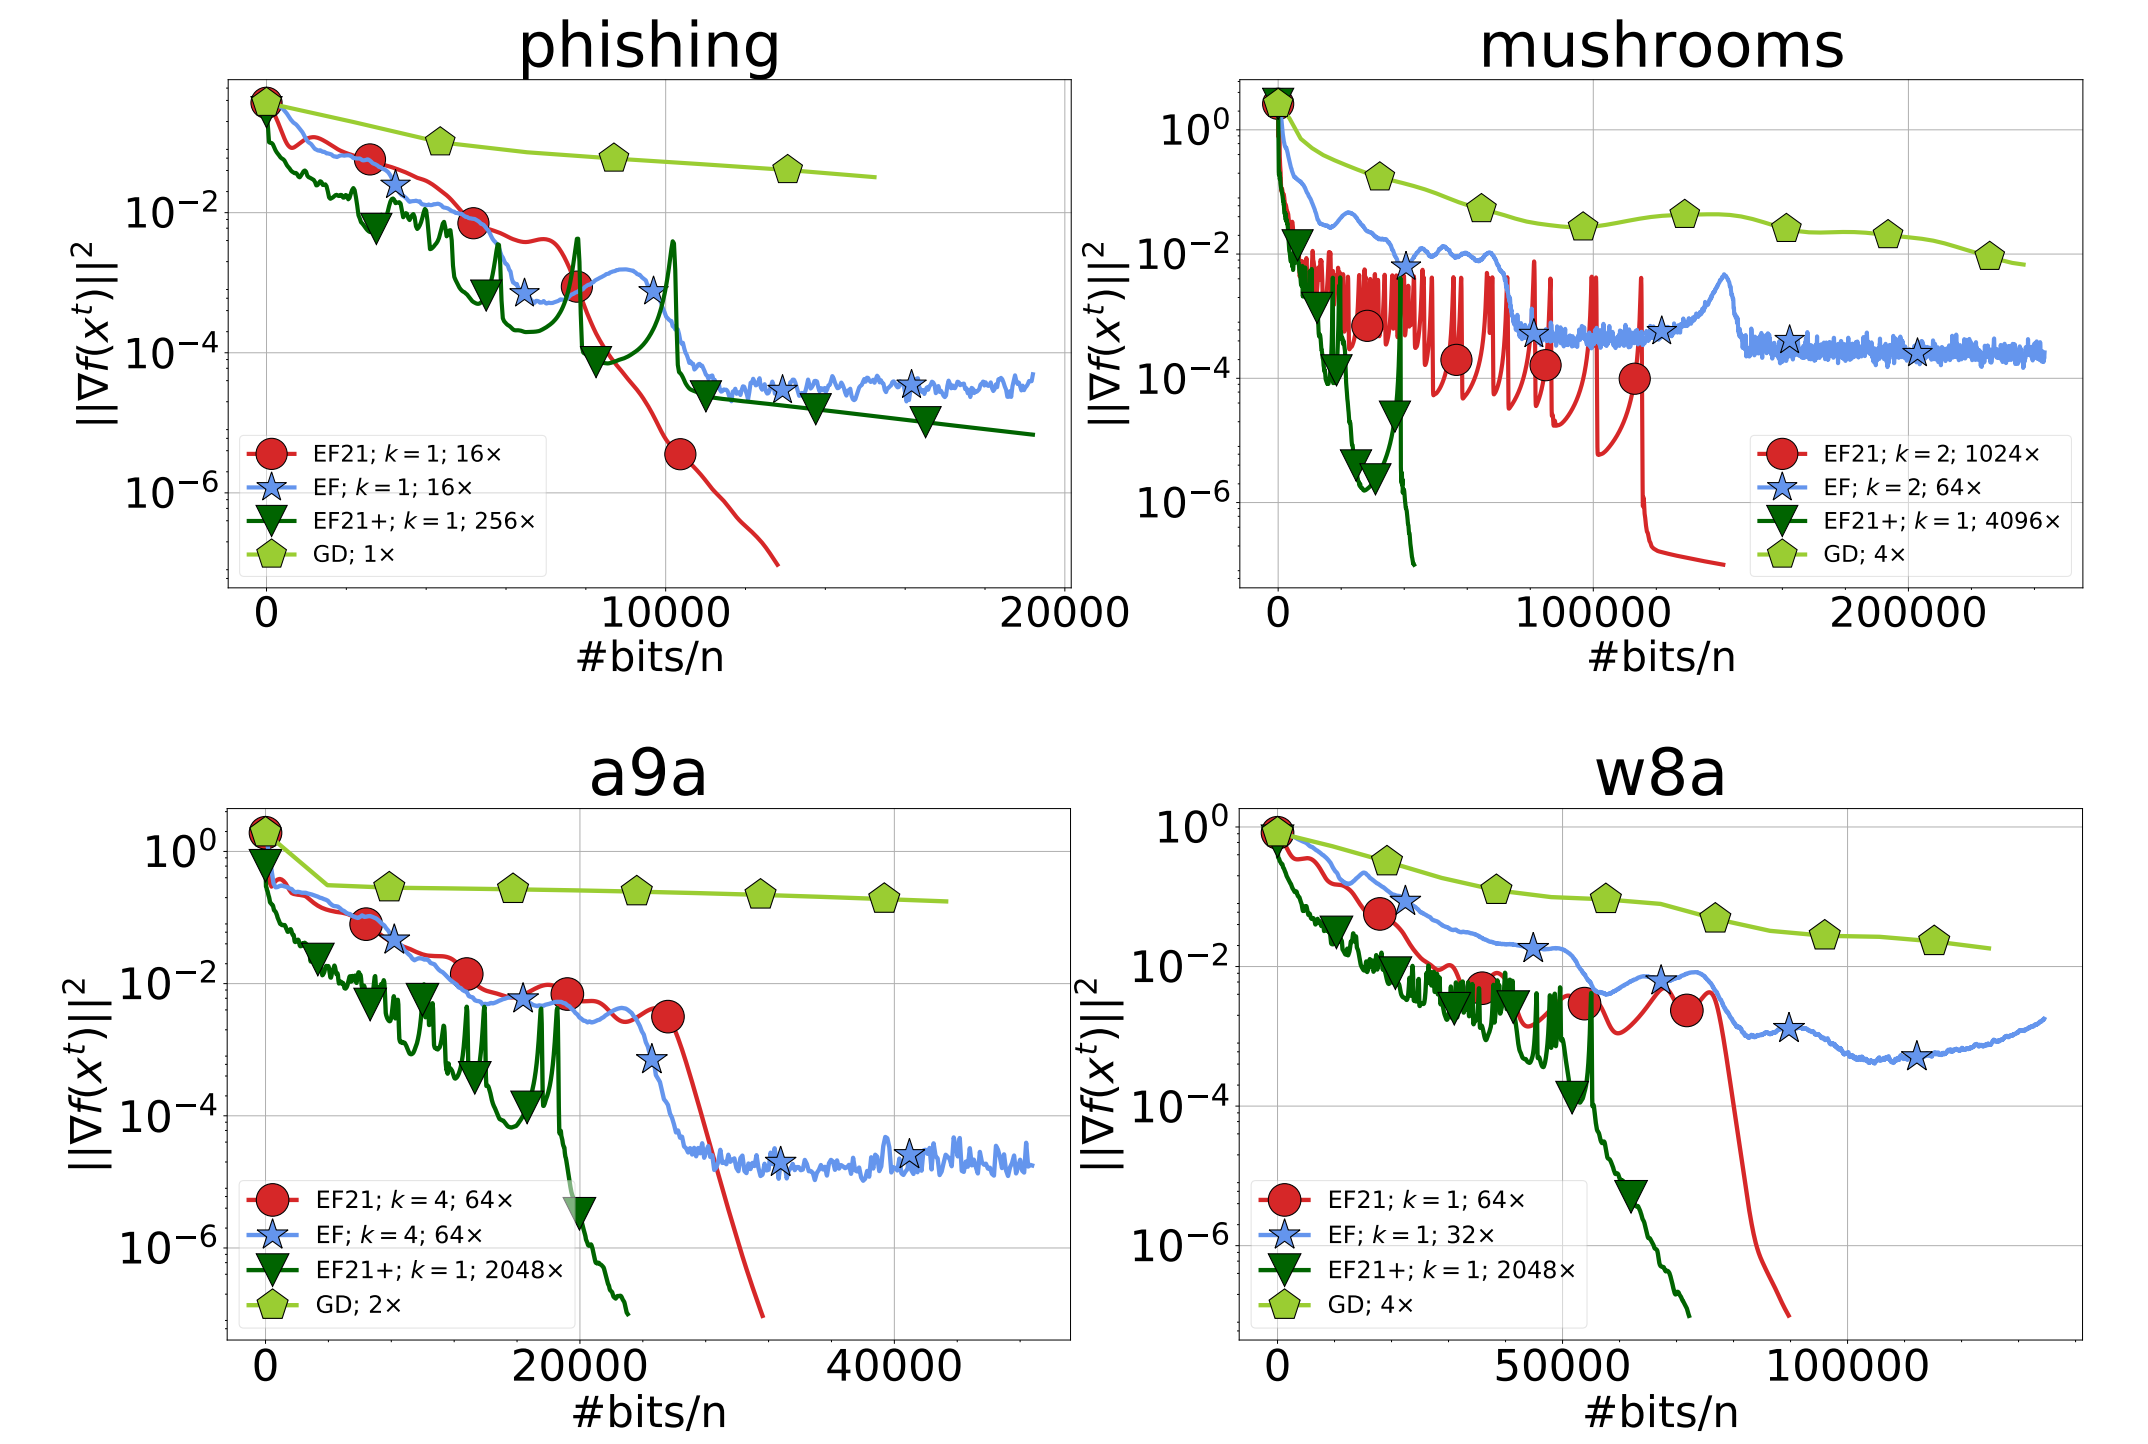

Assumptions	Complexity	Theorem
1	$\mathbb{E} [\ \nabla f(\hat{x}^T)\ ^2] \leq \frac{2(f(x^0) - f^{\inf})}{\gamma T} + \frac{\mathbb{E}[G^0]}{\theta T}$	2
1, 2	$\mathbb{E} [\Psi^T] \leq (1 - \gamma\mu)^T \mathbb{E} [\Psi^0]$	3

## Experiments

**Logistic regression** problem with a **non-convex** regularizer,

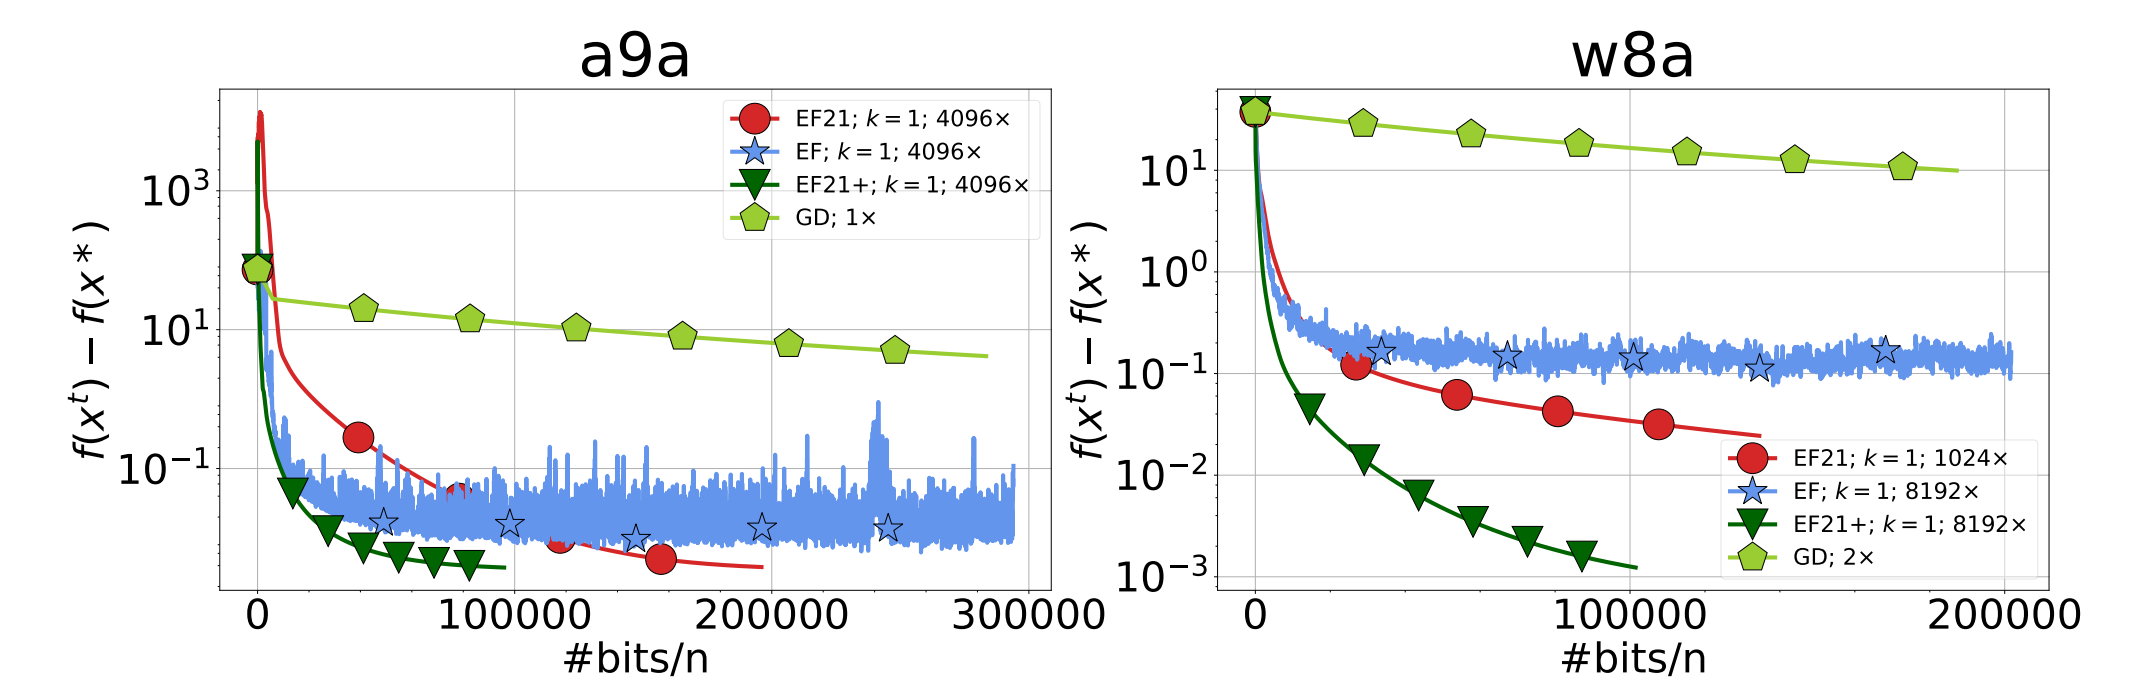

$$f(x) = \frac{1}{n} \sum_{j=1}^n \log \left( 1 + \exp \left( -y_j a_i^\top x \right) \right) + \lambda \sum_{j=1}^d \frac{x_j^2}{1 + x_j^2}, \quad (8)$$

where  $a_i \in \mathbb{R}^d$ ,  $y_i \in \{-1, 1\}$  are the training data, and  $\lambda > 0$  is the regularization parameter.

**Least squares** problem (satisfies PL condition with  $\mu = \sigma_{\min}^2(A)$ )

$$f(x) = \frac{1}{n} \sum_{i=1}^n (a_i^\top x - y_i)^2. \quad (9)$$

By  $1\times, 2\times, 4\times$  (and so on) it is indicated that the stepsize was set to a multiple of the largest stepsize predicted by our theory.  $k = 1$  means that Top-1 compressor was used in the experiment. Both stepsizes and  $k$  were fine-tuned in the experiments above.
